

# Constraining the source properties of individual Terrestrial Gamma-ray Flashes

B. Mailyan, M. Briggs, E. Cramer, G. Fitzpatrick,  
O. Roberts, M. Stanbro, V. Connaughton,  
S. McBreen, P. N. Bhat, J. Dwyer

# Discovery of Terrestrial Gamma-ray Flashes

Each module consisted of both a [NaI\(Tl\)](#) Large Area Detector (LAD) covering the 20 keV to  $\sim 2$  MeV range, 50.48 cm in dia by 1.27 cm thick, and a 12.7 cm dia by 7.62 cm thick NaI Spectroscopy Detector, which extended the upper energy range to 8 MeV, all surrounded by a plastic scintillator in active anti-coincidence to veto the large background rates due to cosmic rays and trapped radiation.

The Burst and Transient Source Experiment (BATSE) detector modules are located at the 8 corners of CGRO.

## The Derivation of the term “TGF”

BATSE was an experiment designed to study high-energy *Celestial* objects.

When TGFs were discovered, I felt it was necessary to emphasize their *Terrestrial*, rather than cosmic, origin.

The word “*Flash*” was meant to imply a shorter duration event than a “*Burst*”. (*Cosmic Gamma-ray Bursts were the primary scientific objective of BATSE.*)

If TGFs were discovered by another instrument, space-borne or otherwise, they would likely have had a different name. e.g. Sprites are not called “Terrestrial” Sprites.

# BATSE

## – On-Board Trigger System (Primarily Hard-wired)

Limited On-Board Data Storage and Telemetry Rate –  
Required a trigger system

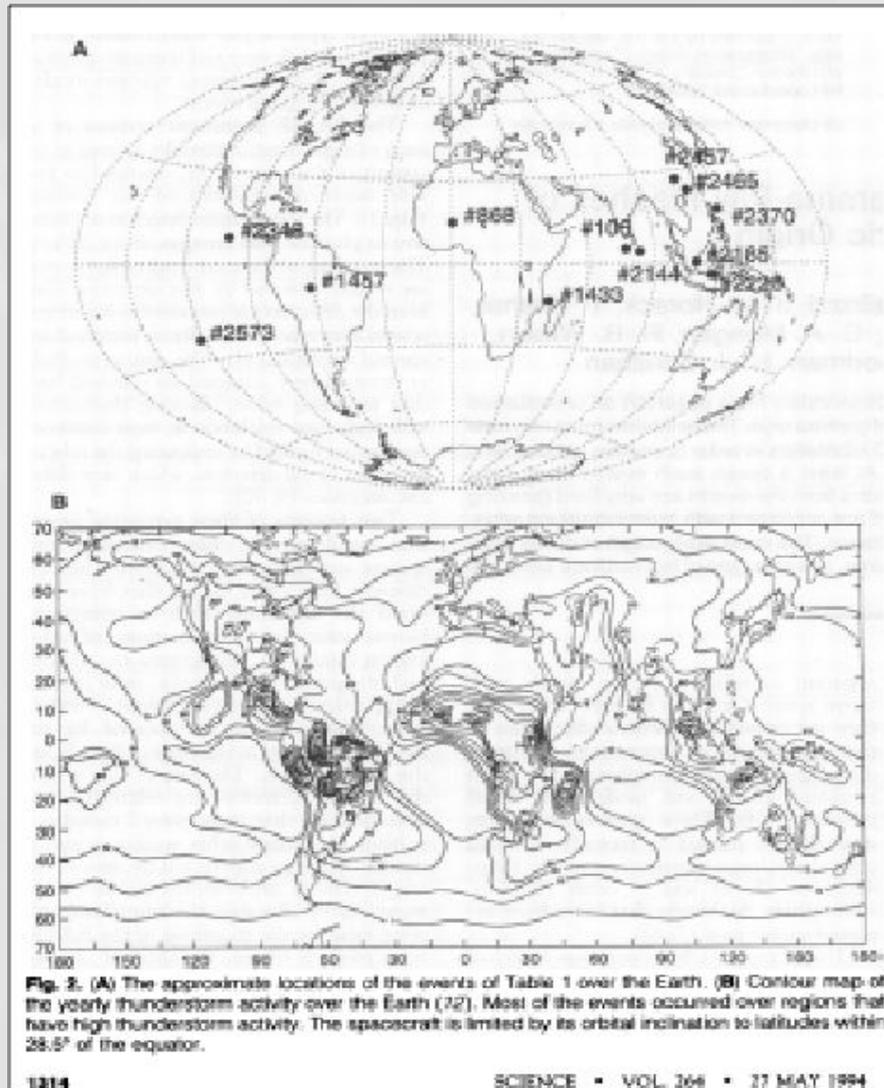

BATSE data system designed with many data types,  
trading energy resolution, time resolution and  
duration, following a trigger

-----

Due to these limitations:

- Most TGFs were missed because they did not trigger within the (wide) 64ms trig. window

SCIENCE - v. 264, p. 1313, May 27, 1994

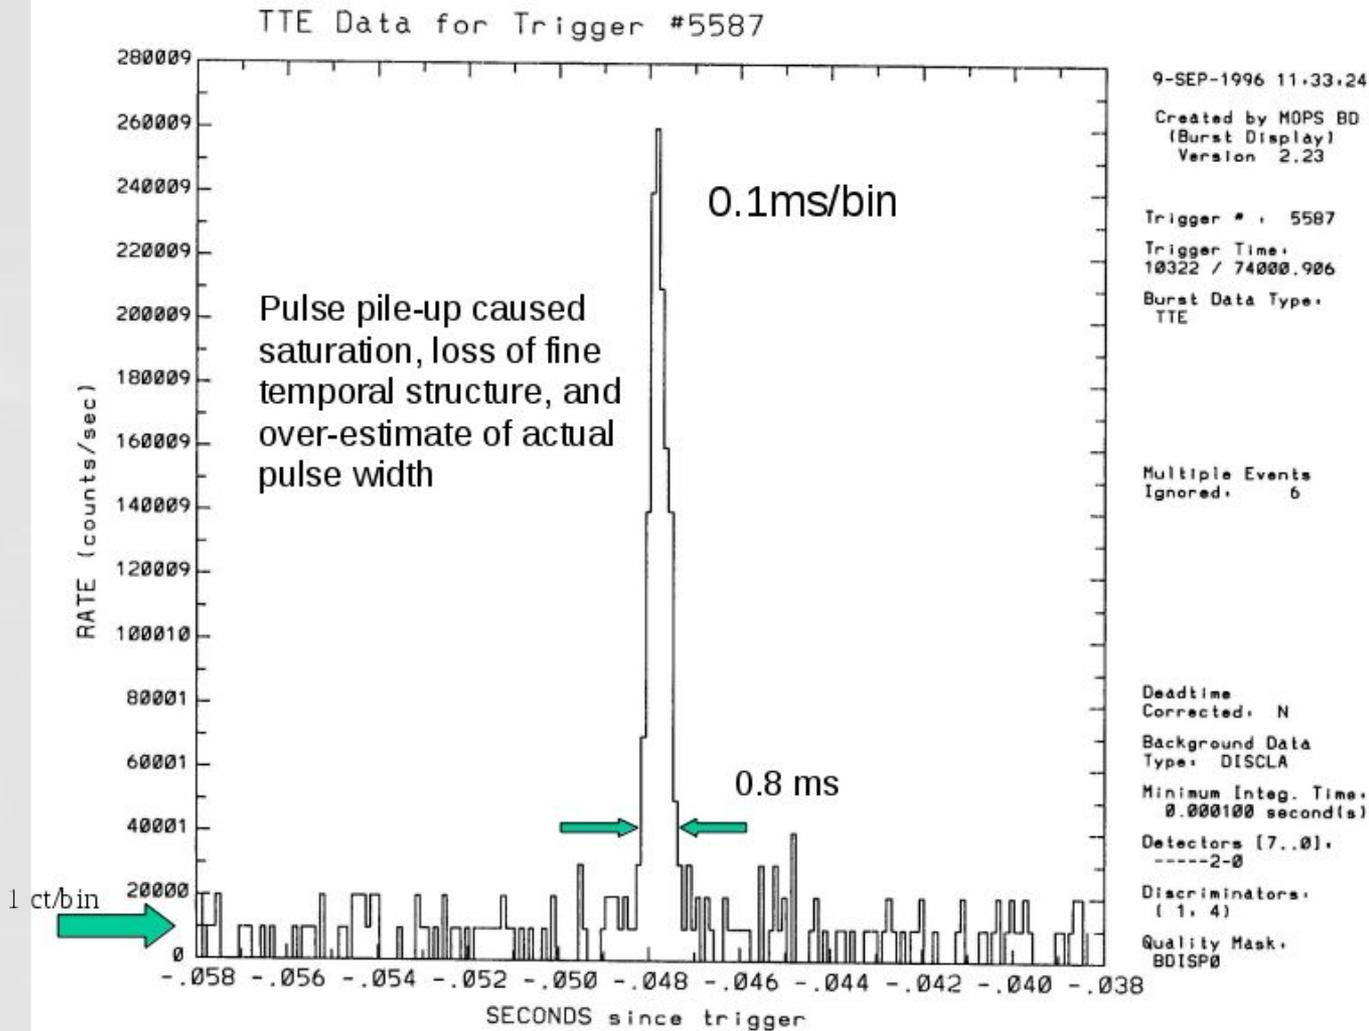

## Discovery of Intense Gamma-Ray Flashes of Atmospheric Origin

Detectors aboard the Compton Gamma Ray Observatory have observed an unexplained terrestrial phenomenon: brief, intense flashes of gamma rays. **These flashes must originate in the atmosphere at altitudes above at least 30 kilometers in order to escape atmospheric absorption and reach the orbiting detectors.** At least a dozen such events have been

## Lightning Leader Model

- The region with subsequent RREA development is provided by the lightning and not the ambient thundercloud electric field e.g., *Celestin et al., 2012*

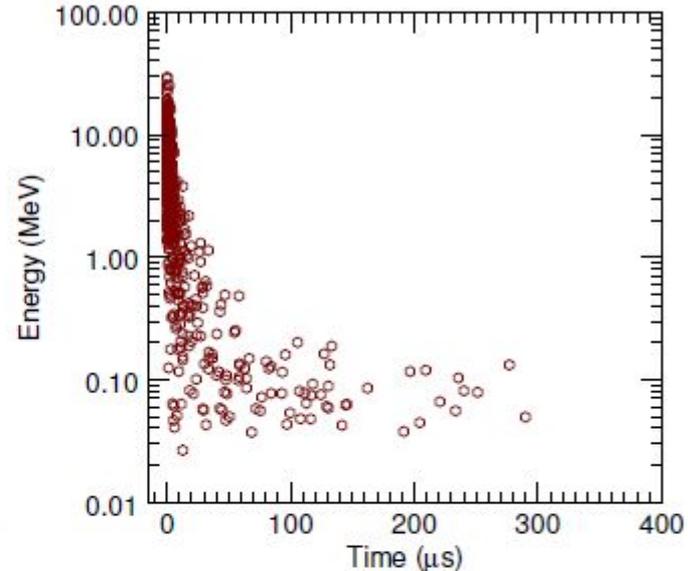

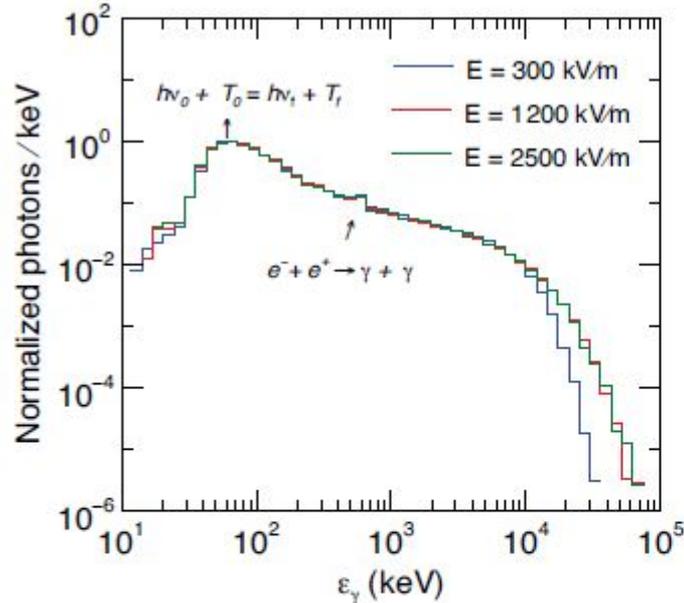

## Relativistic Feedback Discharge Model (RFD)

- As thunderclouds charge, the large scale electric field approaches the relativistic feedback threshold, e.g. *Dwyer 2012*

# Relativistic Runaway Electron Avalanche models

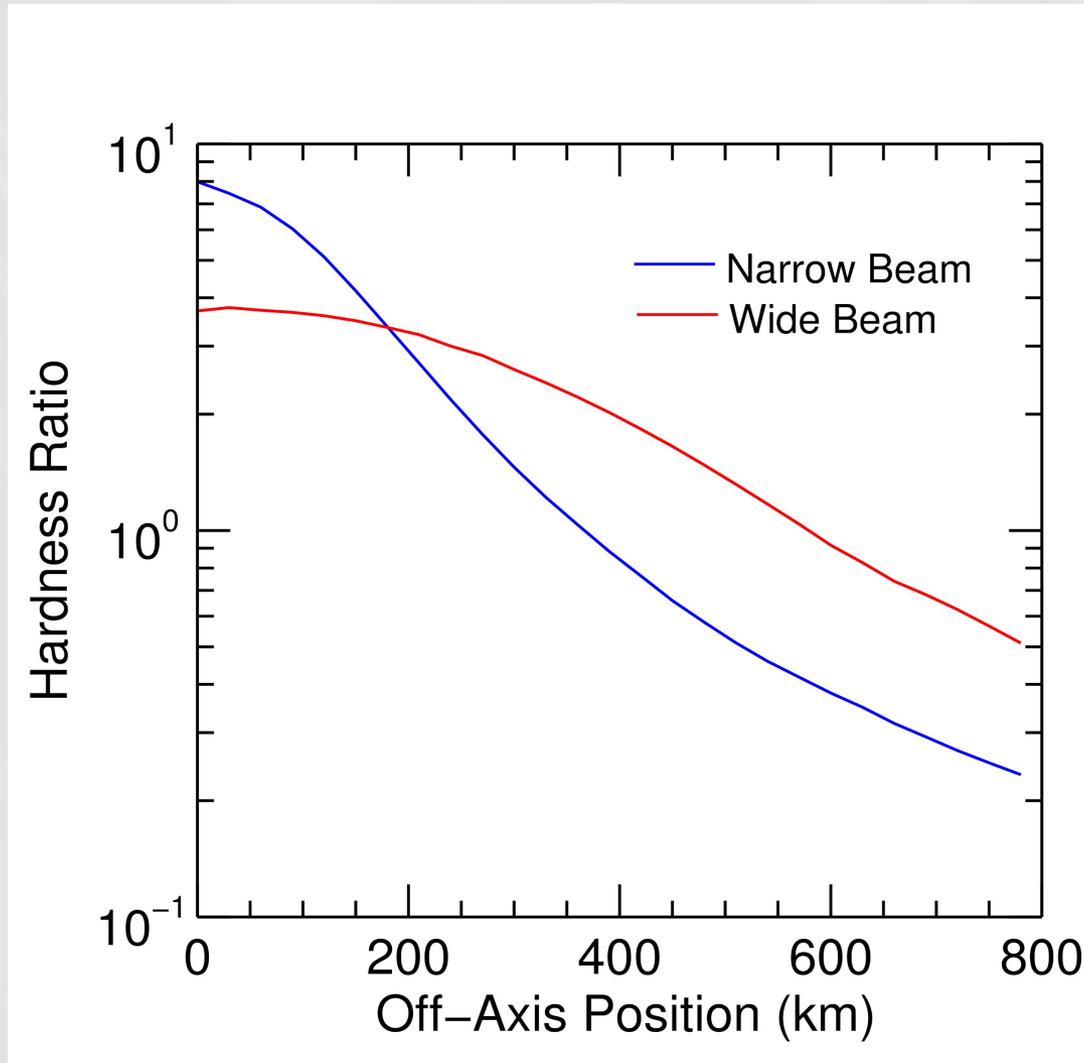

mechanism	name	new feature	flux increase over previous mechanism	discharge time (sec)
Wilson 1925	Runaway electron	Electron energy gain from electric field	$\times 10^1$	~hours
Gurevich et al. 1992	Relativistic runaway electron avalanche	Moller scattering	Up to $\times 10^5$	~10 sec
Dwyer 2003	Relativistic feedback	Backward propagating runaway positrons and Compton scattered x-rays	Up to $\times 10^{13}$	< 0.1 msec

# Atmospheric propagation

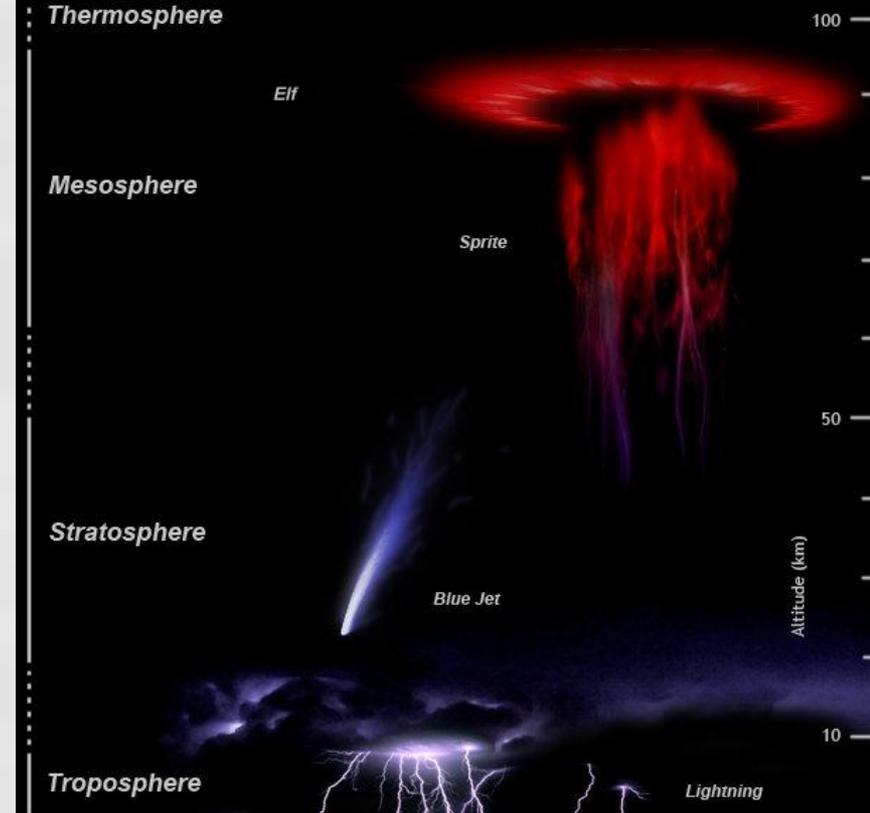

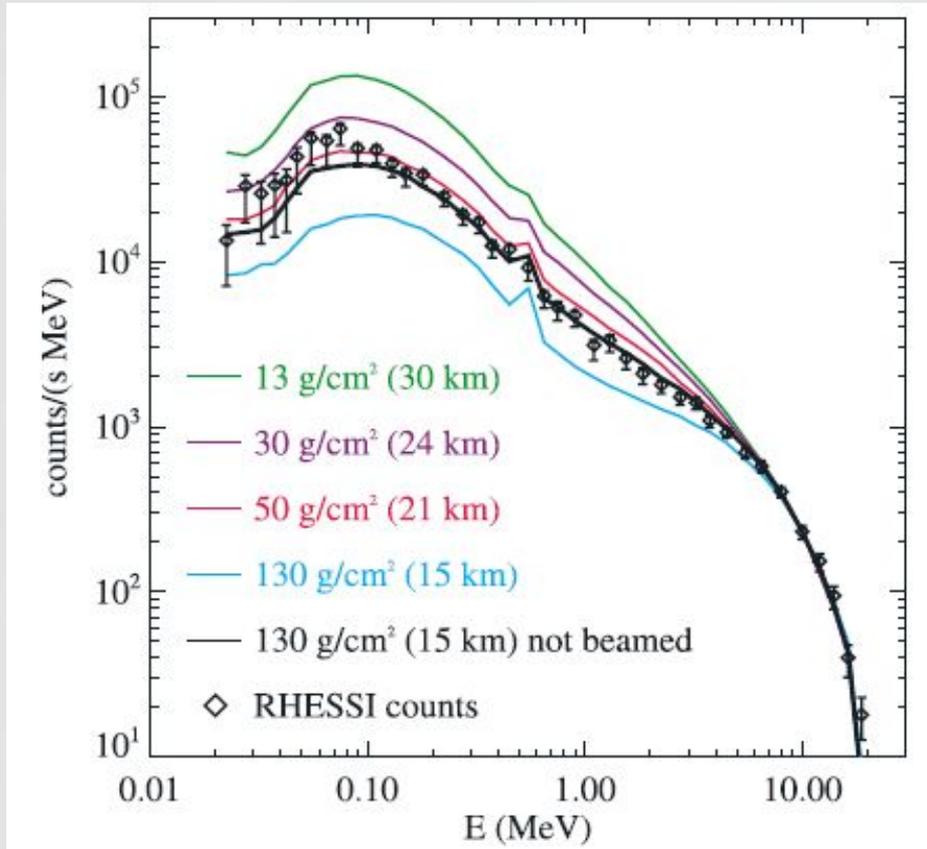

- As the photons propagate through the atmosphere, they are Compton scattered and undergo pair production
- The Compton scattered photons are delayed and produce a tail that can be seen in both simulation and data (Fitzpatrick *et al.*, 2014)

# The effects of compton scattering and beaming geometry

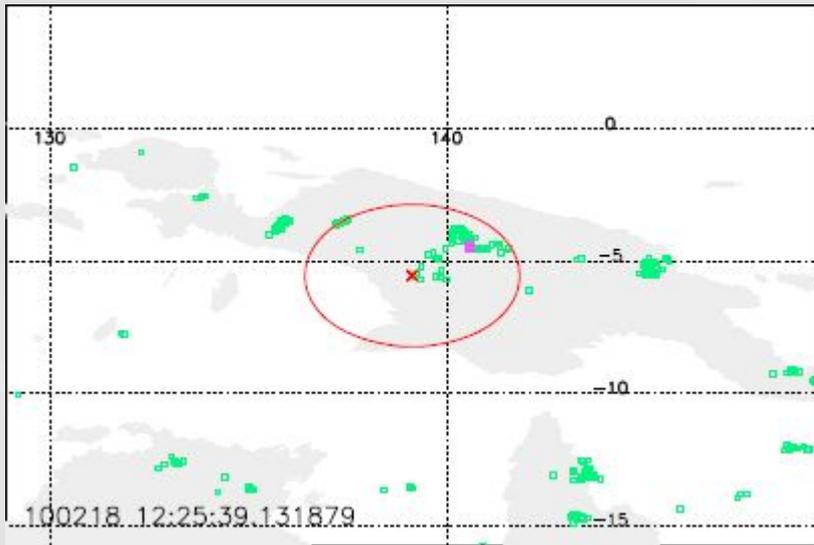

# Spectral Fit of Summed RHESSI TGFs

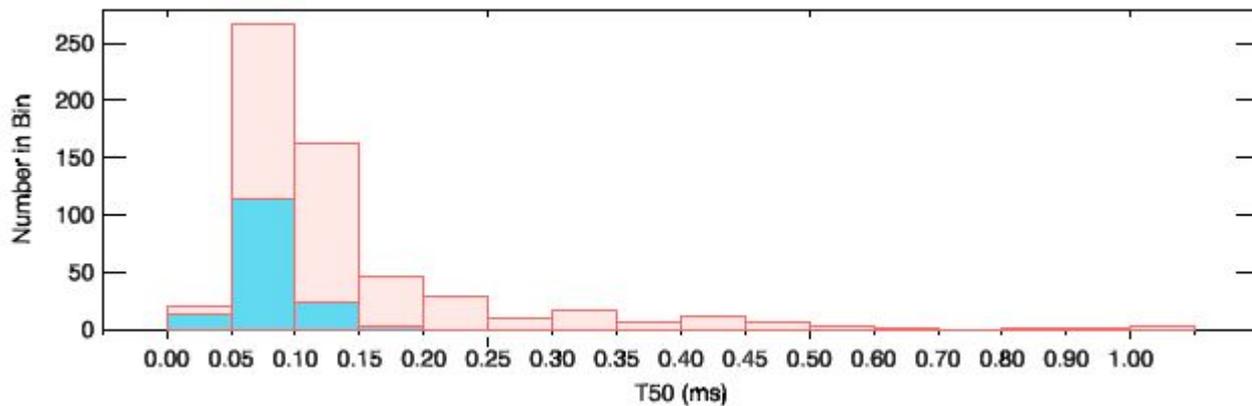

Dwyer and Smith (2005)

# World Wide Lightning Location Network and TGFs

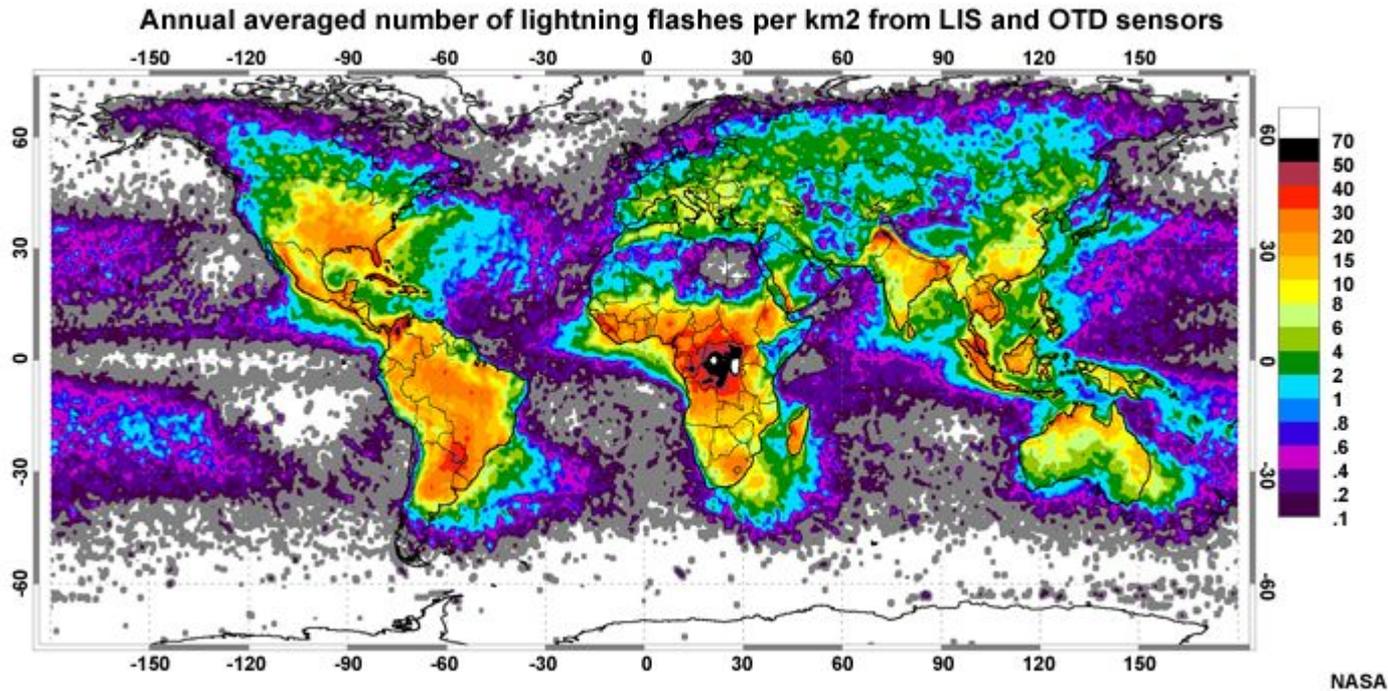

“We infer that the simultaneous VLF discharges are from the relativistic electron avalanches that are responsible for the flash of gamma rays and the nonsimultaneous VLF discharges are from related intracloud lightning strokes”

Connaughton et al., 2013

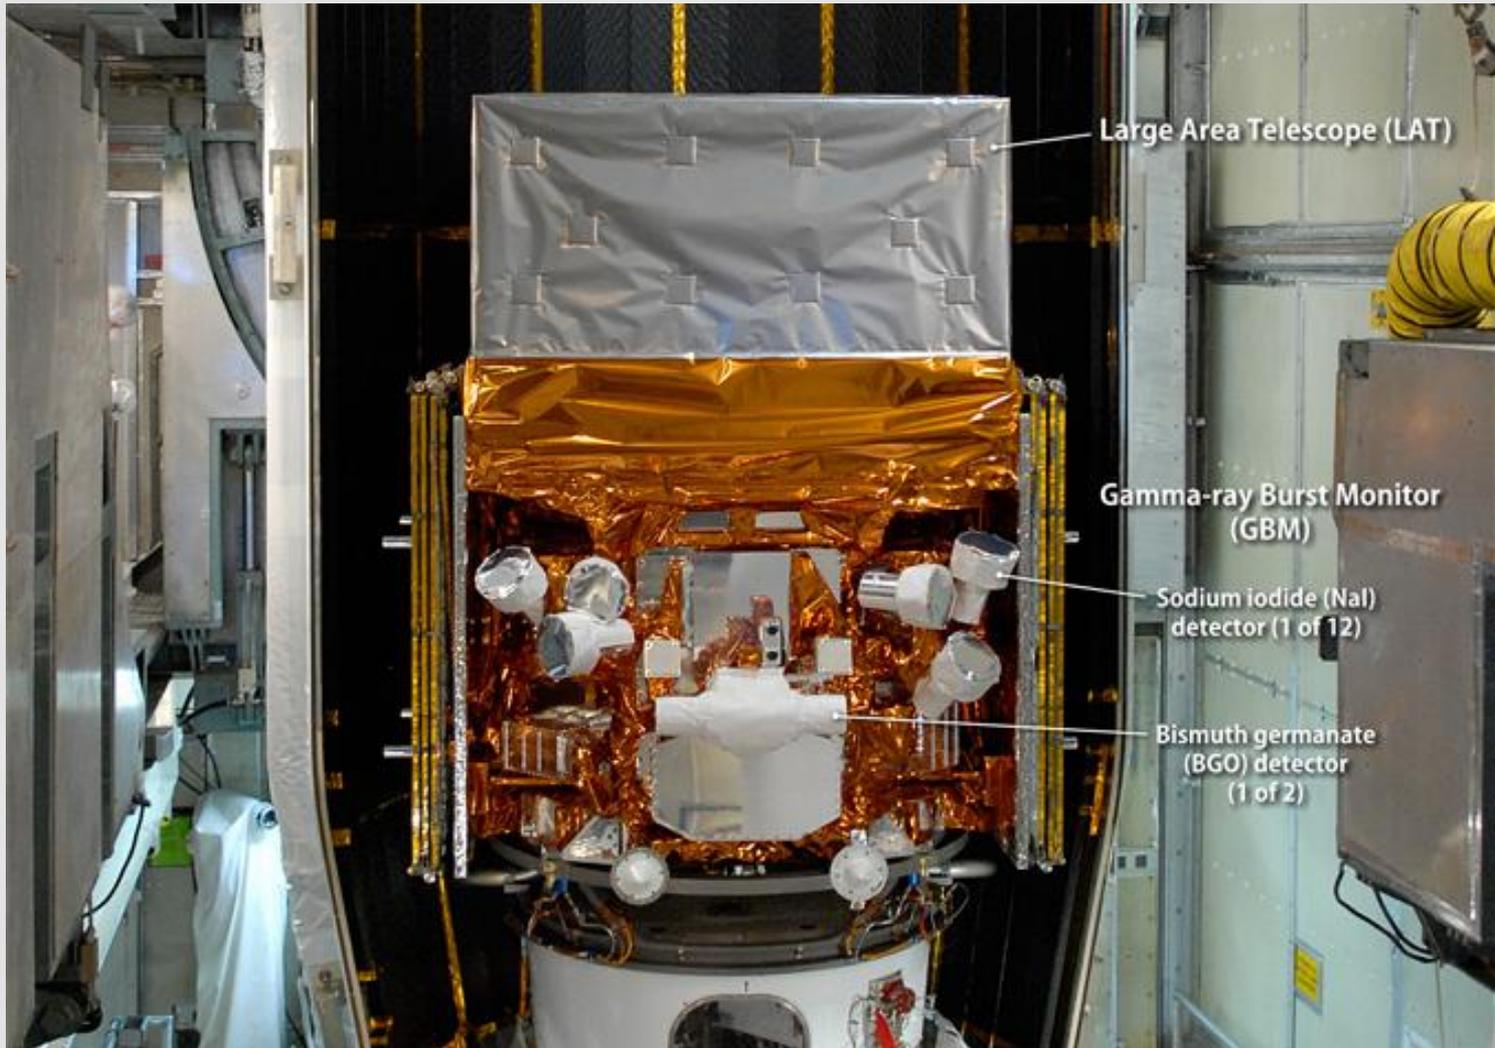

# Lightning flash rates and TGFs

Region	Ratio
Americas	$(4.9 \pm 0.3) \times 10^{-4}$
Africa	$(2.3 \pm 0.2) \times 10^{-4}$
Asia	$(2.7 \pm 0.4) \times 10^{-4}$
Australia	$(8.6 \pm 1.0) \times 10^{-4}$
overall	$(3.8 \pm 0.2) \times 10^{-4}$

# Fermi GBM TGF Catalog

The screenshot shows the Fermi Science Support Center website. The top navigation bar includes the NASA logo, the text "National Aeronautics and Space Administration Goddard Space Flight Center", and "Fermi • FSSC • HEASARC Sciences and Exploration". The main header features the "Fermi Science Support Center" logo and a navigation menu with links for Home, Observations, Data, Proposals, Library, HEASARC, Help, and Site Map. The "Data" section is expanded, showing a sidebar with links for Data Policy, Data Access (including LAT Data, LAT Catalog, LAT Data Queries, LAT Query Results, LAT Weekly Files, and GBM Data), Data Analysis, Caveats, Newsletters, and FAQ. The main content area is titled "GBM Terrestrial Gamma-ray Flashes (TGF) Catalog" and contains the following text:

These tables contain the data of the second Fermi GBM TGF catalog. The catalog contains 3356 TGFs, detected from GBM trigger enabled on 2008 July 11 through 2015 June 23. The catalog is the result of the efforts of the GBM TGF Team with assistance from the Fermi LAT TGF Team.

Several methods detected these TGFs, with increasing sensitivity with time. The initial method was in-flight detection using only the GBM NaI detectors, proceeding to in-flight detection also using the GBM BGO detectors, then to an offline search using time-tagged event (TTE) data. No TGF detection method has ever been removed. The time-tagged event datatype returns information on each photon received by the GBM detectors. With TTE data we can search for TGFs at higher temporal resolution than possible in orbit and achieve a much higher detection rate. Originally the TTE data was collected for portions of the orbit of Fermi, changing on 2012 Nov 26 to production for the full orbit, termed continuous TTE (CTTE). The catalog is more uniform after this date. The initial method was finding ten TGFs per year, now with the offline search of the CTTE we are finding more than 800 TGFs per year.

We also provide software (with documentation) designed for analyzing GBM TTE data, with an emphasis on TGF research.

A paper describing this catalog is in preparation. Until that paper is published, relevant information is provided by Briggs et al. (2013). The correlation of the GBM and World Wide Lightning Location Network (WWLLN) signals is described in Connaughton et al. (2010, 2013).

Please cite this catalog as G. Fitzpatrick et al., in preparation. For questions, please contact Michael.Briggs@uah.edu

### The Catalog

The catalog consists of six tables and datasets. The same TGF can appear in several tables. Different ID styles are used to distinguish between the tables: "oTGF" is used for TGFs in the Offline Search Table, "tTGF" for TGFs in the Trigger Table and "TEB" for TGFs in the Terrestrial Electron Beams Table, even when the entries are the same TGF.

- **Offline Search Table.** The Offline Search Table contains information for 3348 TGFs detected by the ground-based offline search of the TTE data. Most TGFs of the Trigger Table are also included in this table, however, eight of the triggered TGFs are not included because they are not found by the offline search. The parameters in the Offline Search Table are described below.
- **Trigger Table.** The Trigger Table contains information for 579 brighter TGFs that were detected in orbit by the GBM flight software. The content of the Trigger Table is described below.
- **Terrestrial Electron Beams Table.** The TEB table lists the 24 TGFs that might have been detected as electron/positron beam events. One entry in the table is the reliability of the classification as a TEB. Also included are maps of the lightning activity underneath Fermi and at the magnetic footpoint. The TEB table is documented below.

# The Catalog

The catalog consists of six tables and datasets. The same TGF can appear in several tables. Different ID styles are used to distinguish between the tables: “oTGF” is used for TGFs in the Offline Search Table, “tTGF” for TGFs in the Trigger Table and “TEB” for TGFs in the Terrestrial Electron Beams Table, even when the entries are the same TGF.

- [Offline Search Table](#). The Offline Search Table contains information for 3348 TGFs detected by the ground-based offline search of the TTE data. Most TGFs of the Trigger Table are also included in this table, however, eight of the triggered TGFs are not included because they are not found by the offline search. The [parameters in the Offline Search Table](#) are described below.
- [Trigger Table](#). The Trigger Table contains information for 579 brighter TGFs that were detected in orbit by the GBM flight software. The [content of the Trigger Table](#) is described below.
- [Terrestrial Electron Beams Table](#). The TEB table lists the 24 TGFs that might have been detected as electron/positron beam events. One entry in the table is the reliability of the classification as a TEB. Also included are maps of the lightning activity underneath Fermi and at the magnetic footprint. The [TEB table is documented](#) below.
- [Comments and Special Cases Table](#). There are a few TGFs with missing values (which are denoted with “NULL” in the tables) due to unusual analysis issues or missing data. These cases are described in this table. If we are able to obtain a missing value, or if corrections are needed, updated tables will be posted.
- [WWLLN Associations Table](#). The WWLLN Associations Table contains results for 1049 TGFs for which temporally-coincident radio signals of the [World Wide Lightning Network \(WWLLN\)](#) were found. These associations provide accurate localizations of the TGFs. More [information on this table](#) is provided below.
- [WWLLN Lightning Maps and Data files](#). This dataset consists of maps of the lightning detections made by WWLLN for  $\pm 10$  minutes relative to the TGF time. Also included are text data files with the positions and times of the lightning sferics on the maps. The [content of these maps and data files](#) are described below.

**WWLLN locations are provided so Fermi GBM DRMs can be generated!**

# Terrestrial Electron Beams

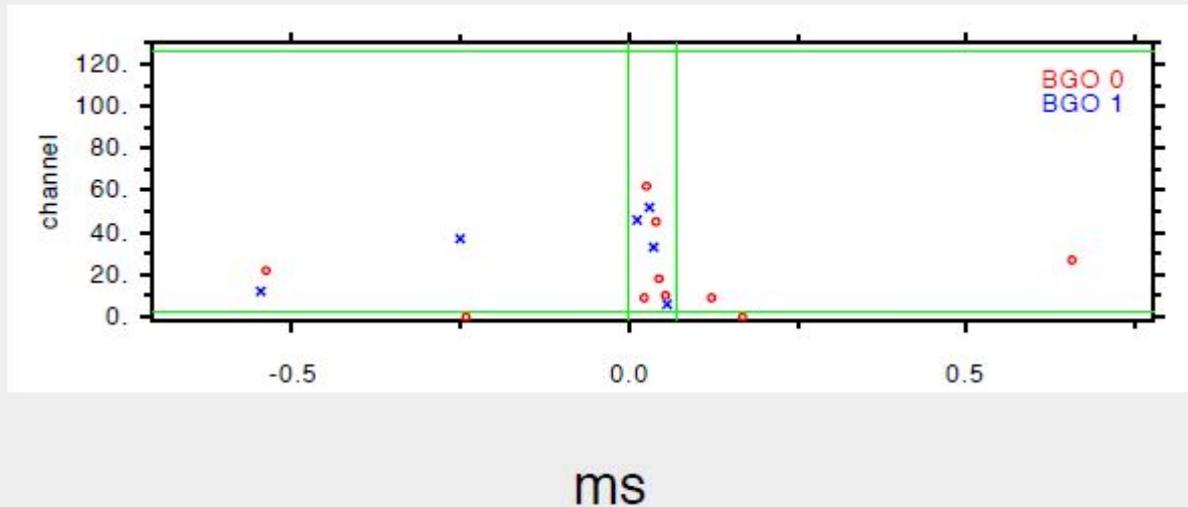

Briggs et al., 2011

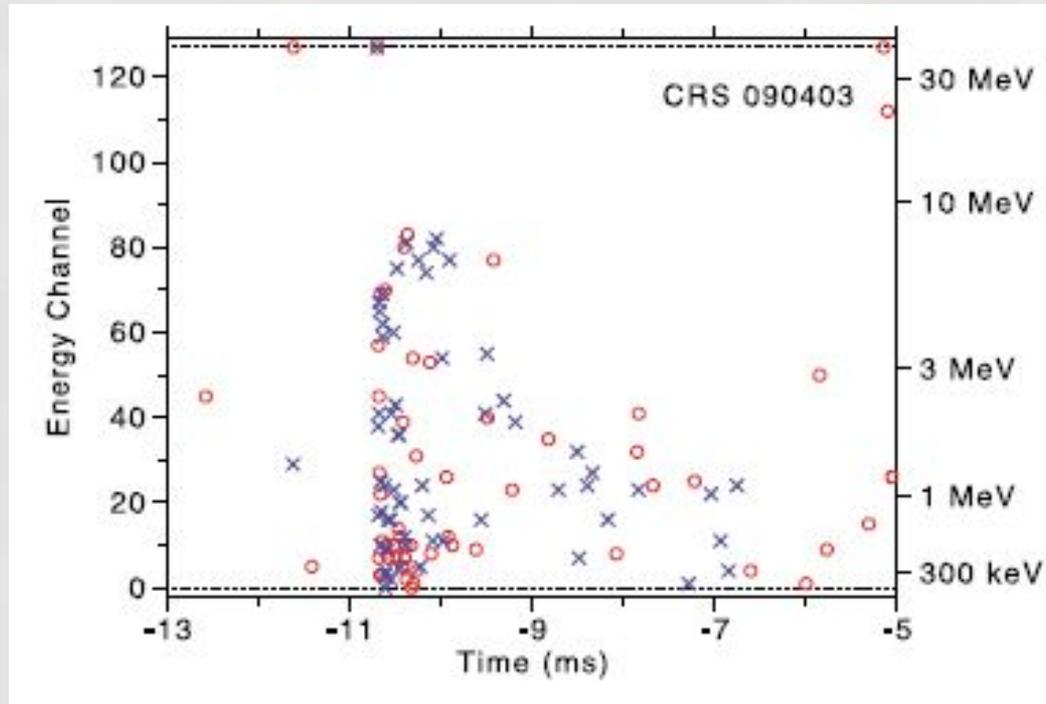

## Criteria of the Offline Search of Continuous Time-Tagged Events (CTTE) for TGFs:

- $\geq 4$  counts in each BGO

Cosmic ray rejection!

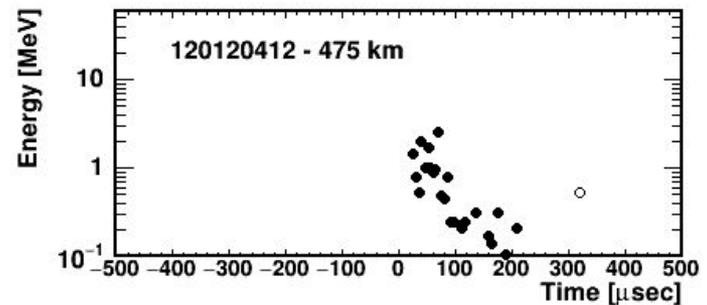

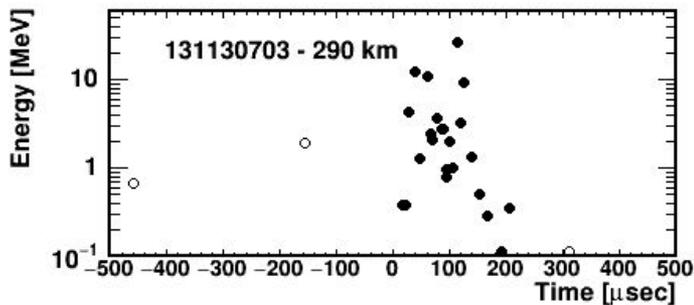

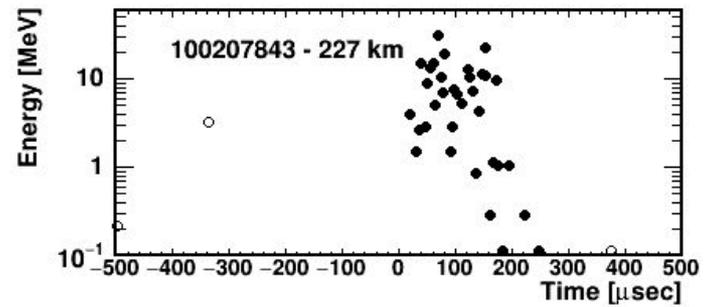

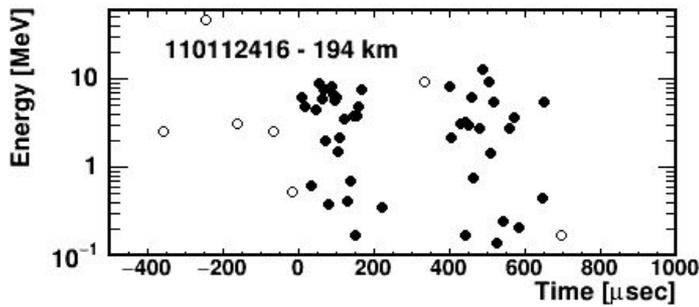

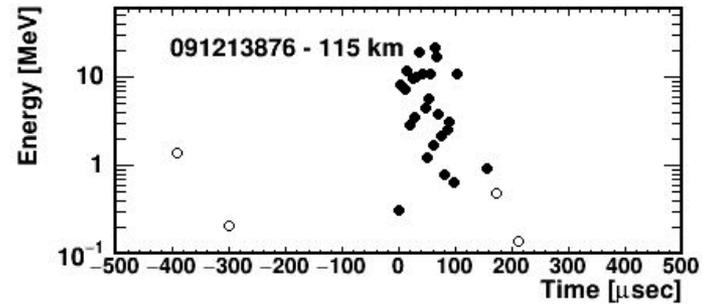

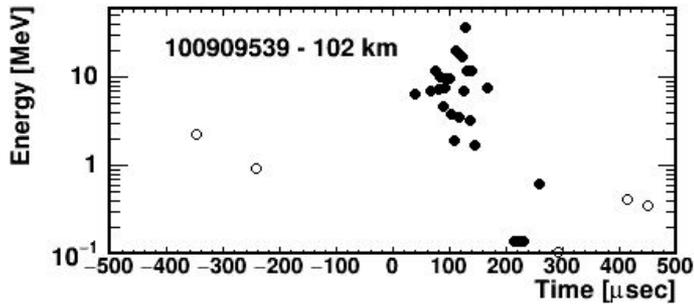

# Cosmic ray rejection

Briggs et al., 2010

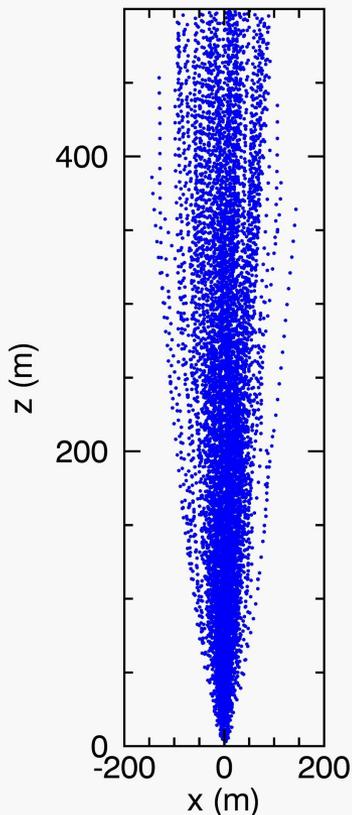

# Individual TGF analysis

# Data selection

- We have used Fermi GBM data of bright TGFs from BGO detectors ( $>20$  photons  $> 200$  keV). Azimuth angle within 60 degrees.
- From 2008 to 2015 about 3400 TGFs were observed. WWLLN and ENTLN provided the TGF radio locations for about 1000 TGFs.
- Choosing the bright events with favorable positions till the end of 2013 resulted in a sample of 46 TGFs.

# Modeling

The acceleration of electrons and consequent emission of gamma rays with further propagation of the particles were simulated using REAM code (Dwyer, 2007).

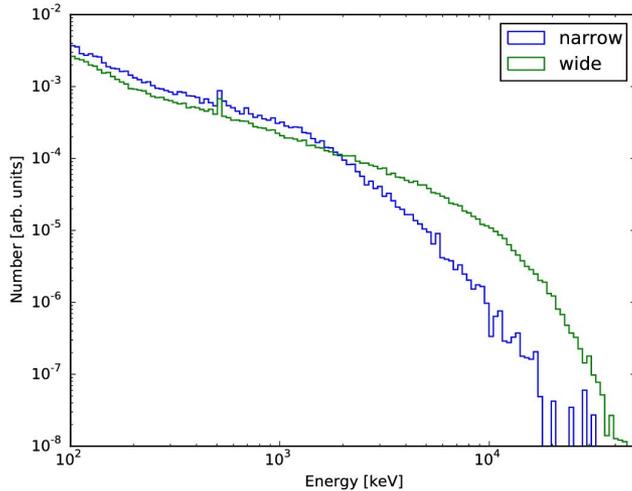

4 kV/cm field was used for 5 avalanche lengths and 10000 seed electrons.

11.6, 13.4, 16.0, 20.2 km narrow and wide sources were tested.

The altitudes correspond to atmospheric column densities given by MSIS model used in REAM code.

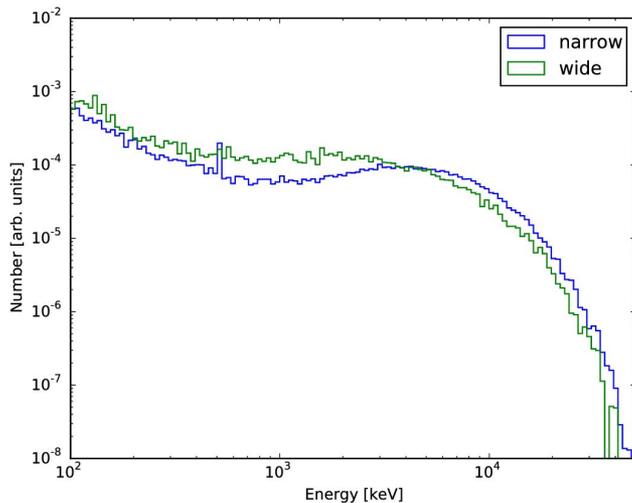

[http://omniweb.gsfc.nasa.gov/vitmo/msis\\_vitmo.html](http://omniweb.gsfc.nasa.gov/vitmo/msis_vitmo.html)

# Modeling

High offset

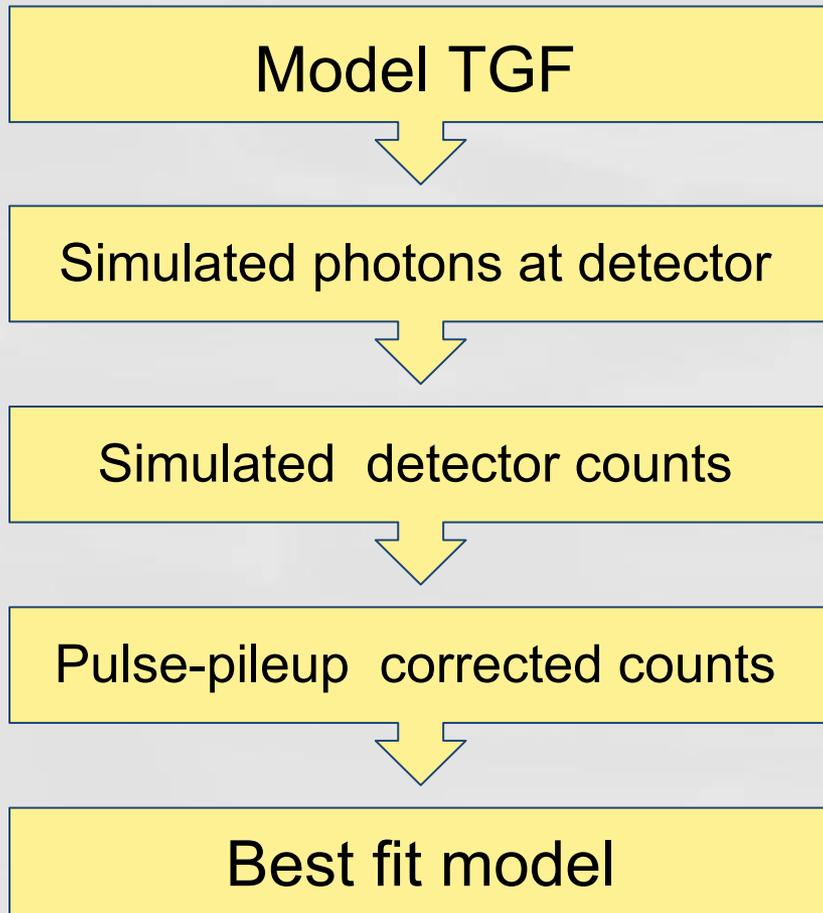

Simulated photon energy spectra at spacecraft altitude for **narrow** and **wide** models the source altitude of 13.4 km and at the source-nadir offset of 475 km (top) and 102 km (bottom).

Low offset

**Wide** models, having broader photon angular distribution, provide more high energy particles at large offsets.

# Fit procedure

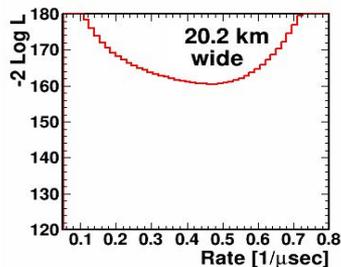

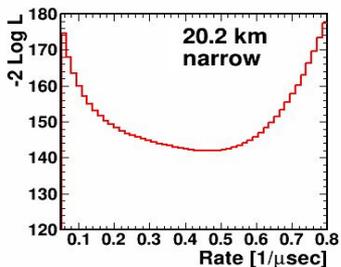

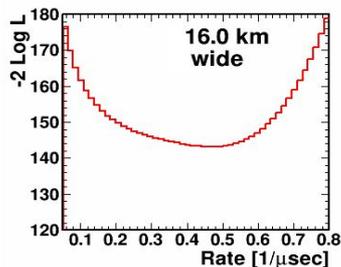

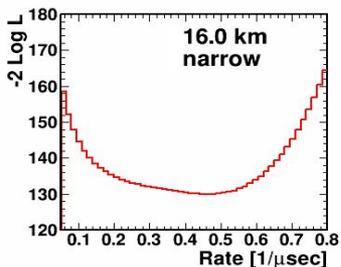

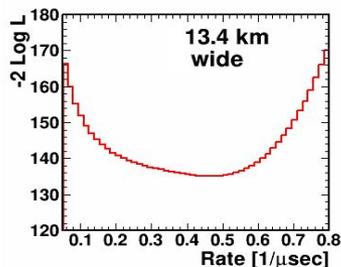

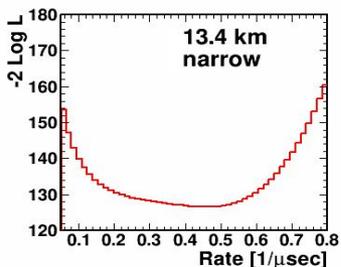

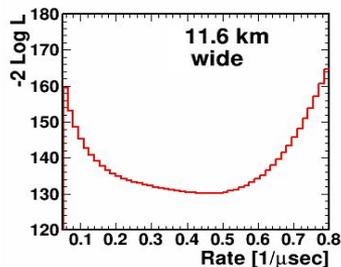

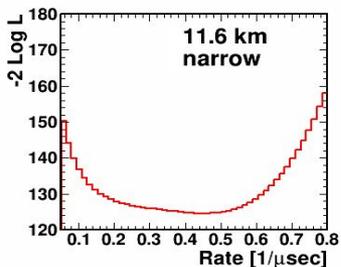

Relativistic Electron Avalanche Model (REAM).

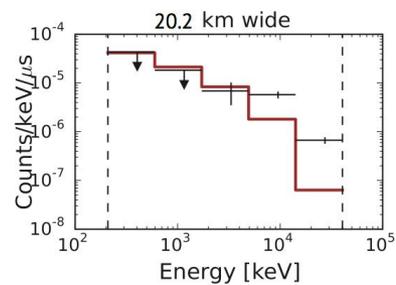

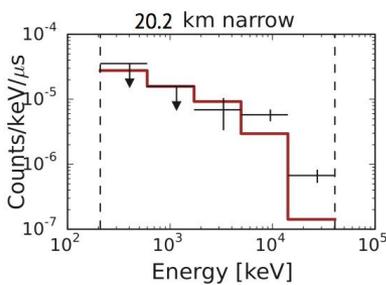

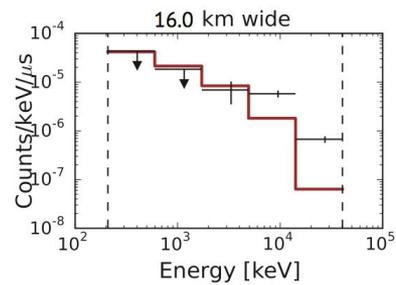

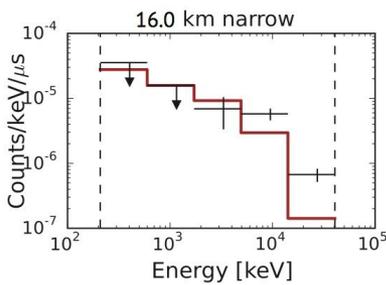

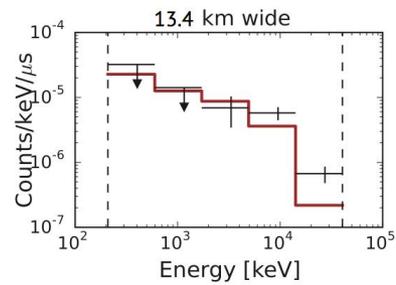

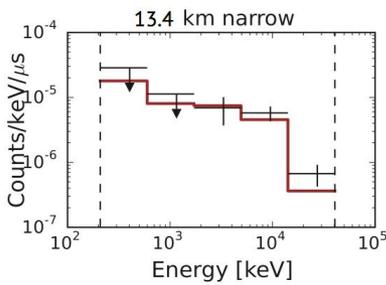

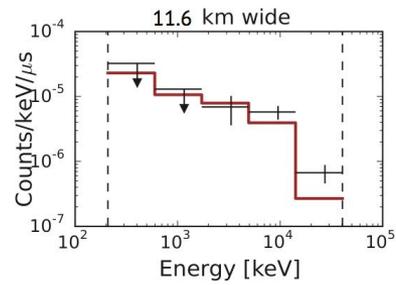

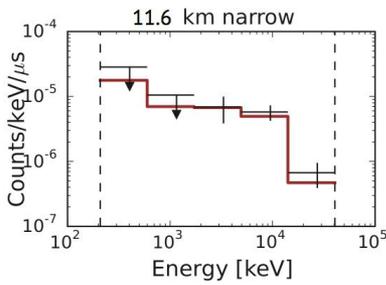

Calculating detector response matrices using radio location.

Pulse Pile-up (PPU) code developed by Chaplin et al., (2013).

Likelihood analysis: iterating over the models choosing acceptable/rejected ones.

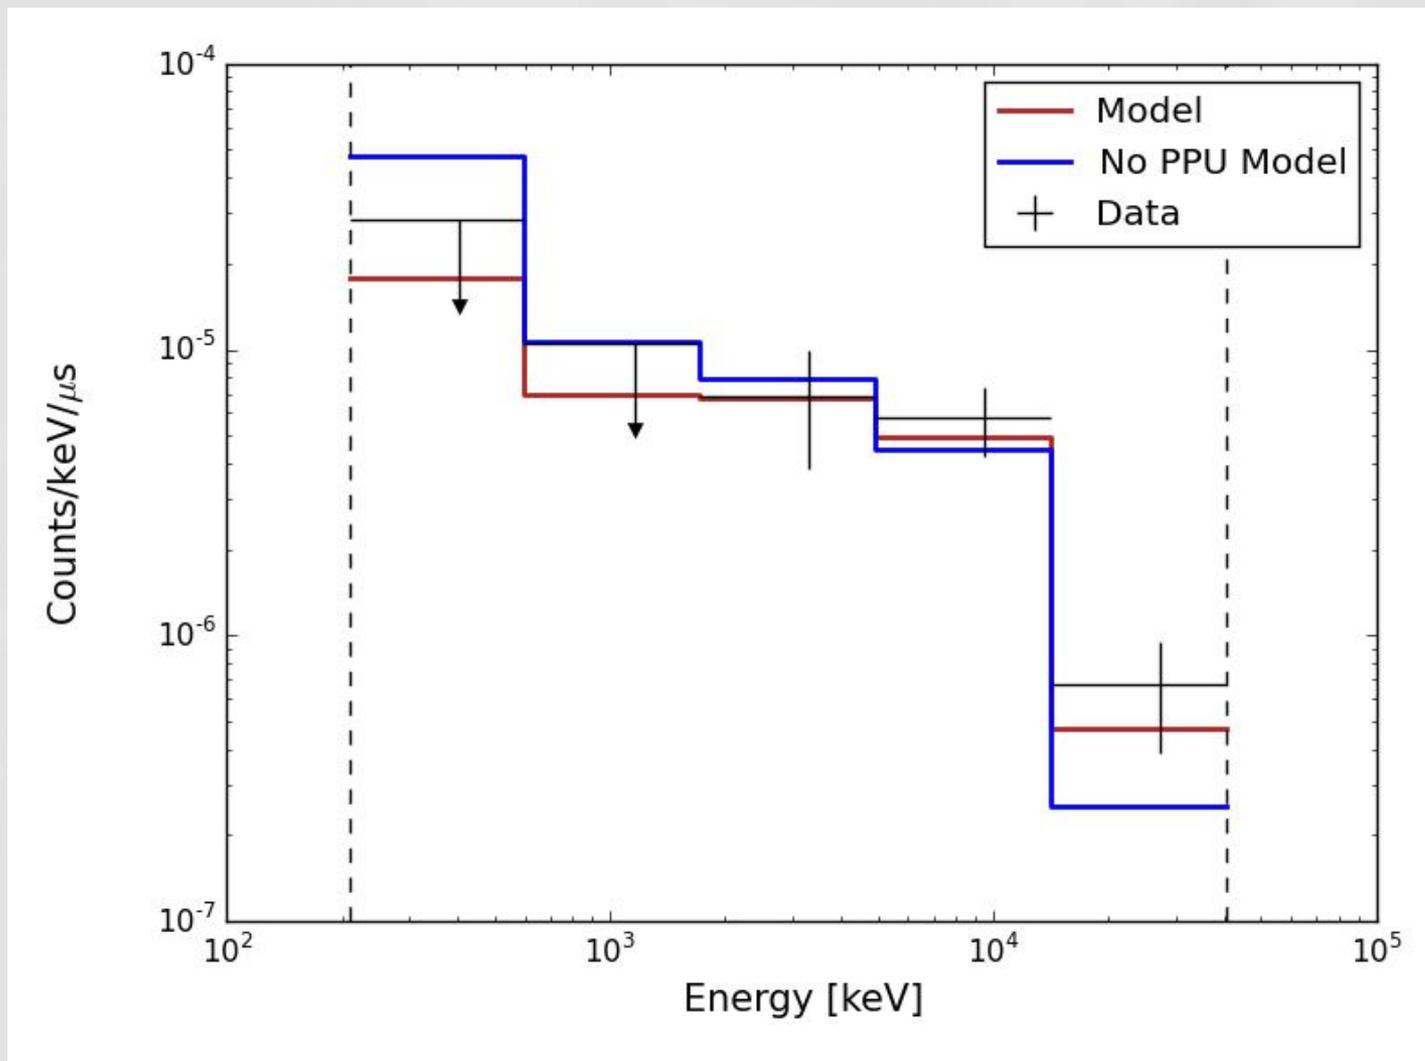

Results: TGF100909539 (102 km source-nadir offset )- Likelihood analysis

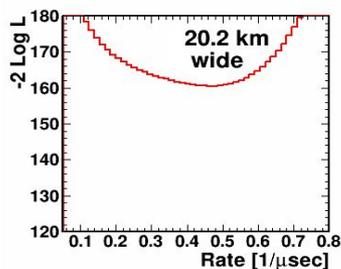

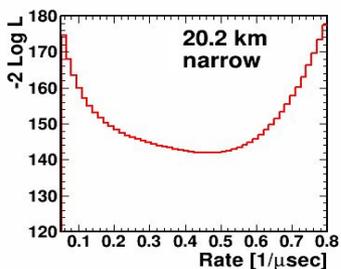

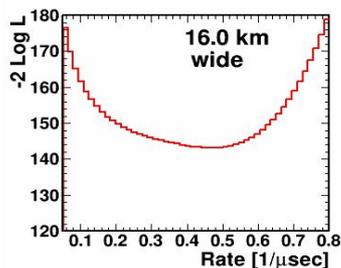

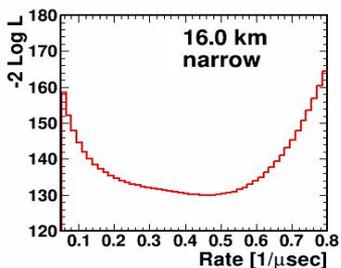

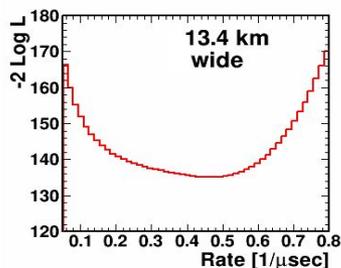

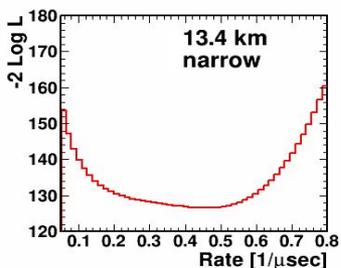

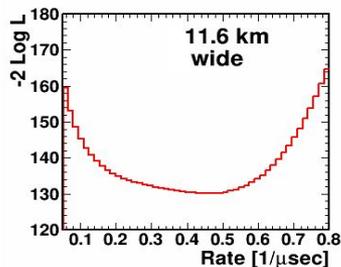

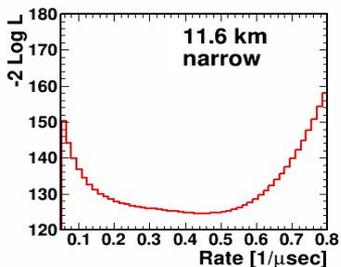

## Results: TGF100909539

Low altitude narrow models can explain the observed hard spectrum.

# Results: TGF100909539 best fit model and pulse pile-up effects

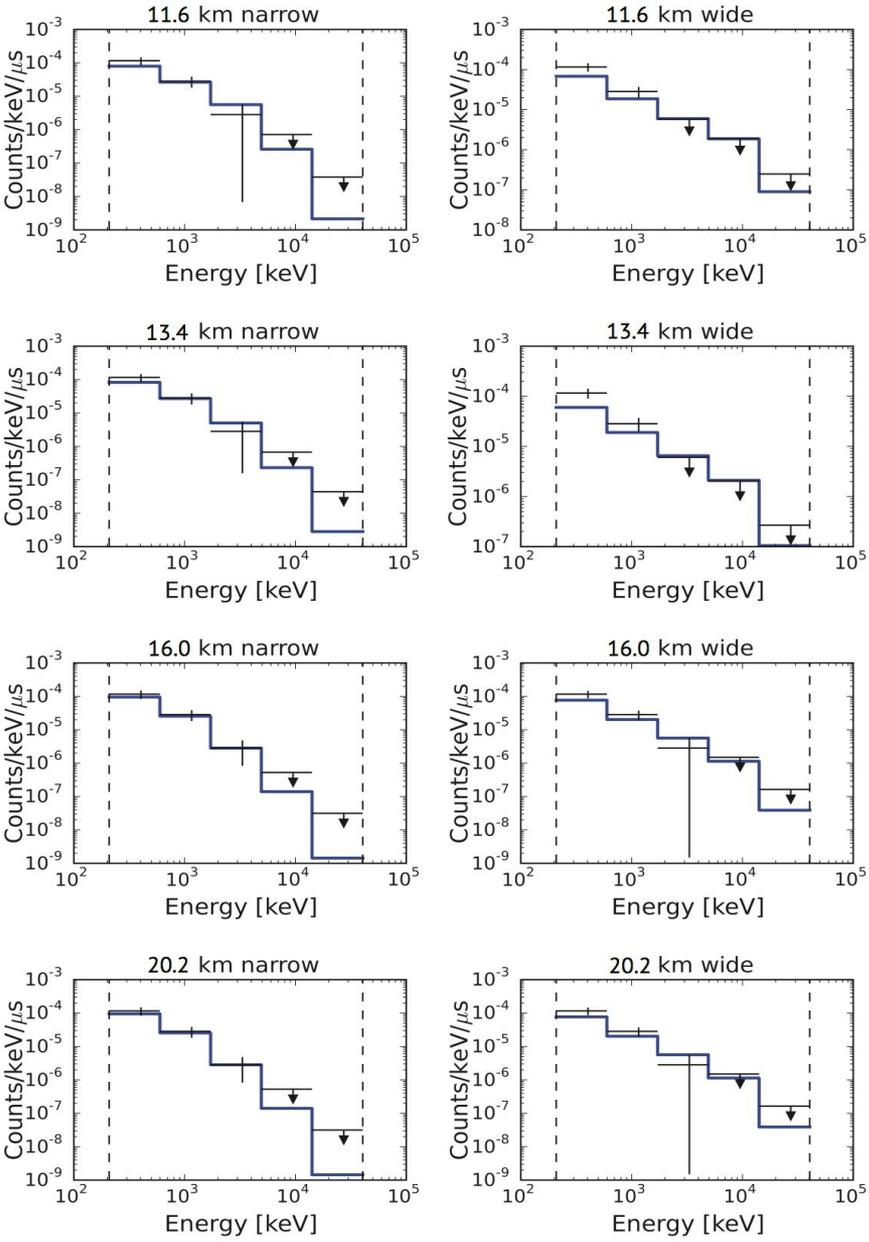

Results: TGF100909539 (102 km source-nadir offset )- Likelihood analysis

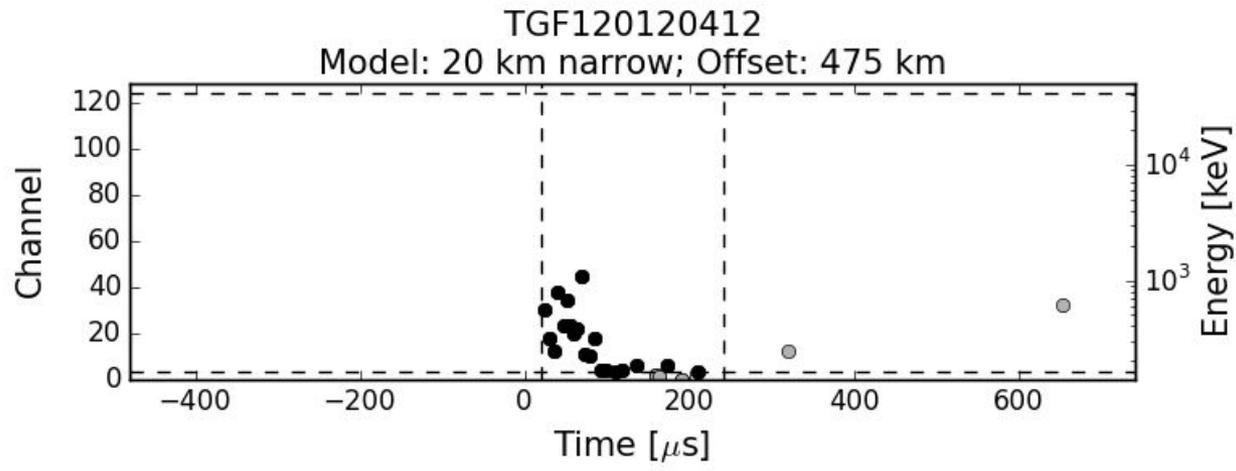

Deep narrow models are the best fit to the data!

# Results: TGF120120412 (475 km source-nadir offset)

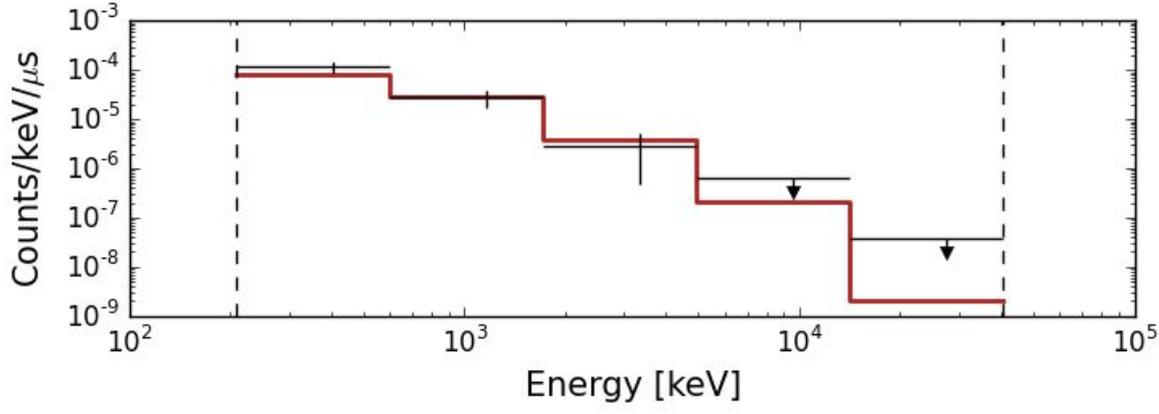

High altitude narrow models and low pulse pile-up can explain the observed soft spectrum.

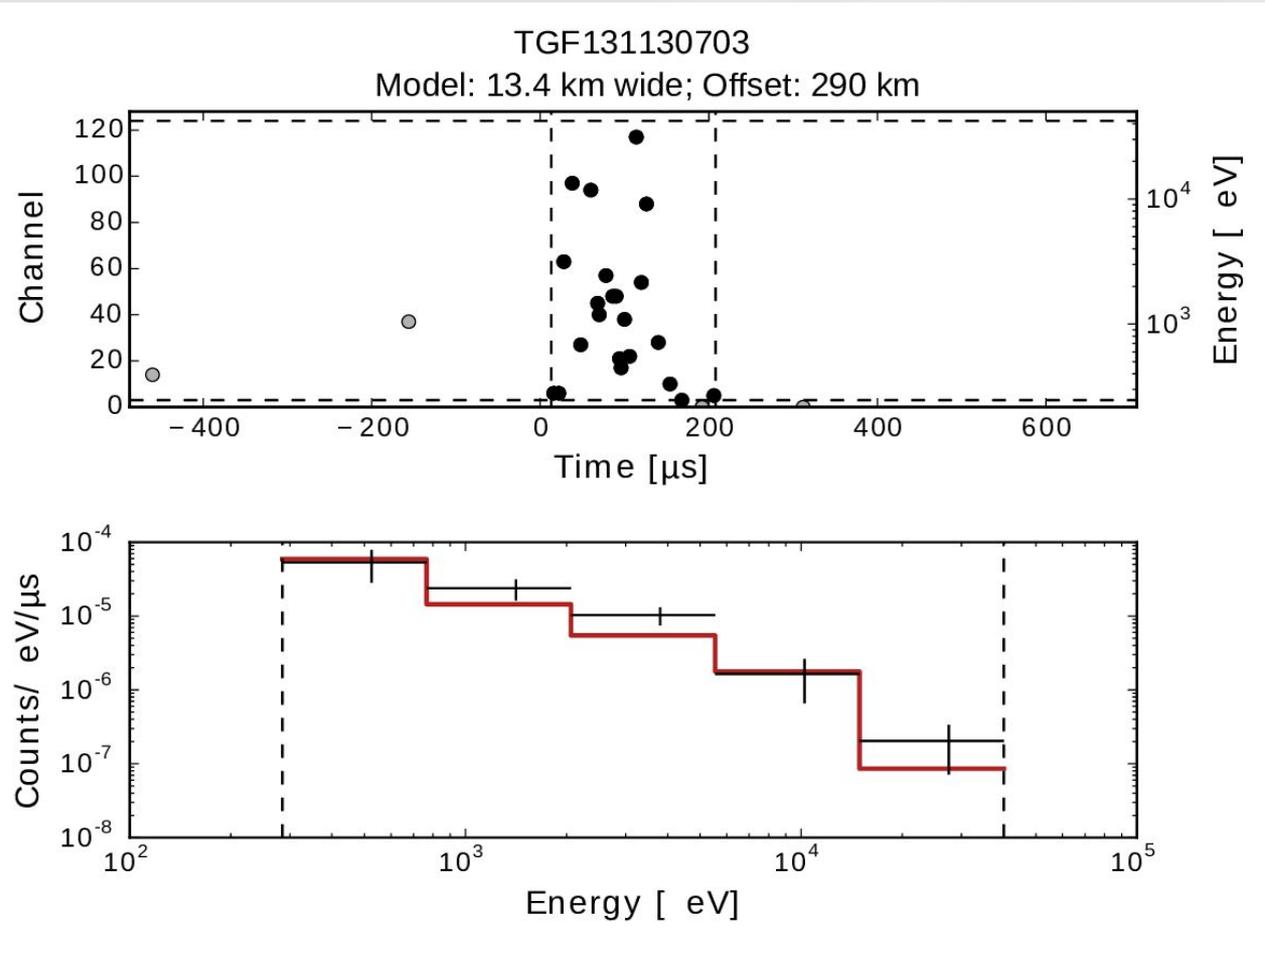

# Results: TGF120120412

- High altitude
- Narrow beam
- Small pulse pile-up

# Results: TGF131130703 - Wide beams are the best fit!

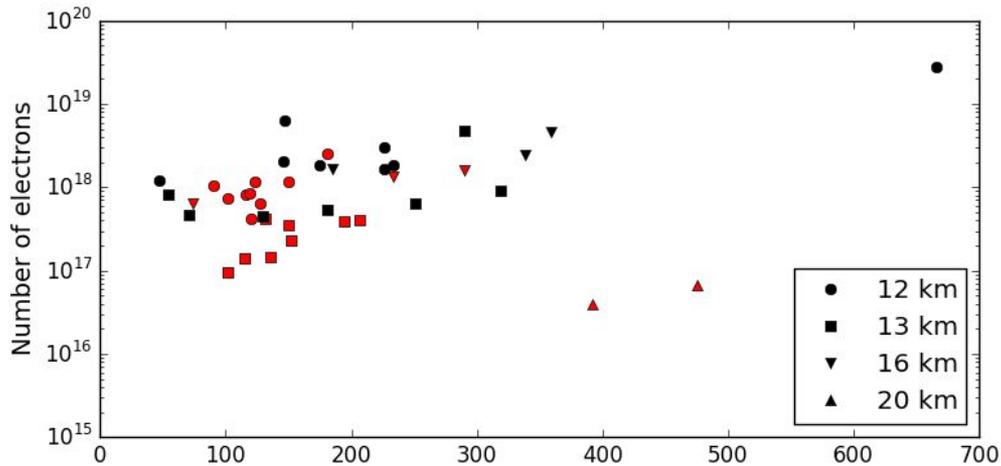

Wide beams send more high energy photons to the spacecraft!

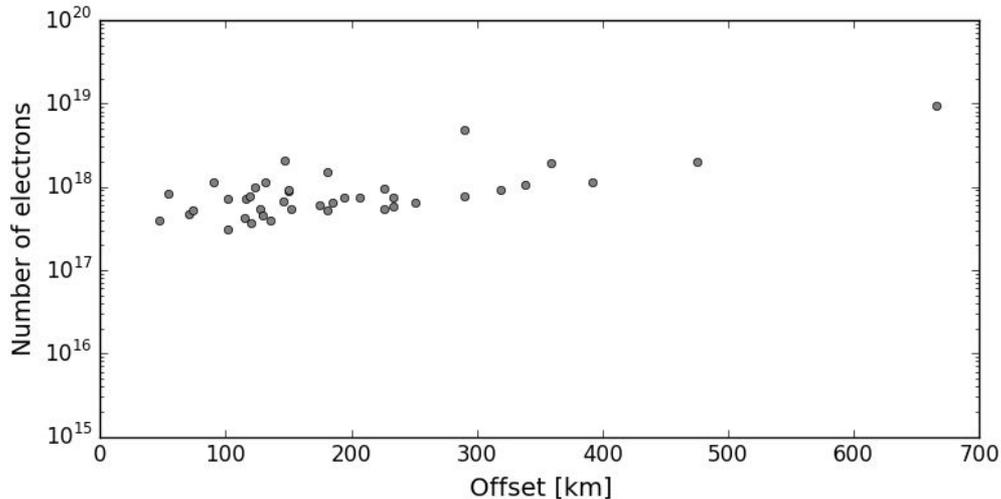

# Summary

- Of the 46 TGFs studied, 4 are unambiguously best fit by narrow models and another 2 unambiguously best fit by the wide beam model.
- For 6 TGFs, it was not possible to obtain a good fit.
- For most TGFs in our sample, it is not possible to distinguish between the narrow and wide beam models. However, the fact that some can be constrained is important as all previous published results based on summed TGF spectra have favored the wide beam models.

# Summary: intrinsic brightness of TGFs

Assuming the best fit model source altitude

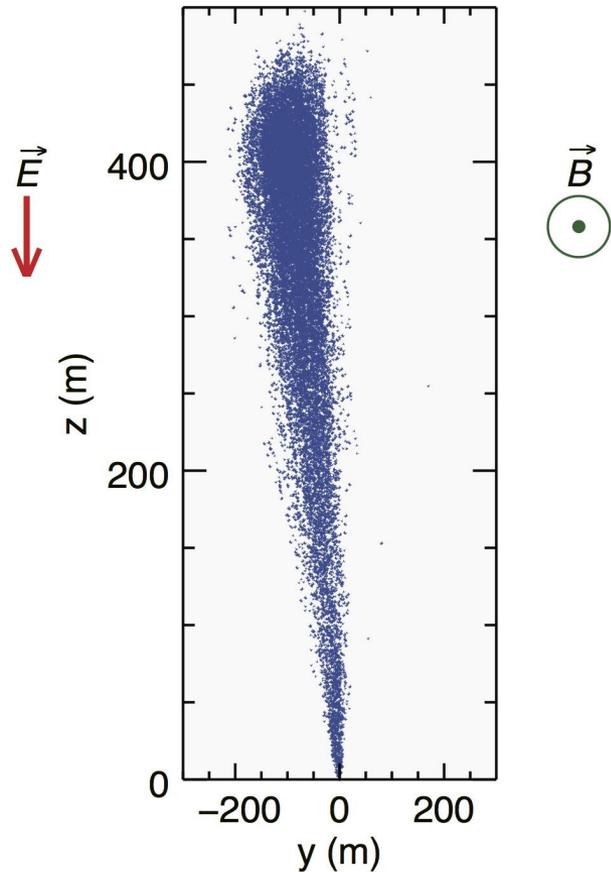

Assuming 13 km source altitude wide model

Narrow and wide beam models are indicated by red and black colors respectively

# Conclusions

- Observations exhibit spectral diversity of TGFs
- Some TGFs can be best fit by narrow (**large-scale RREA in organized electric fields**), some others by wide beam models (**acceleration at lightning leader tips or large-scale RREA in chaotic electric fields**)
- Spectral analysis of individual TGFs put constraints on the source altitudes
- Pulse pile-up effects

# Tilted beams and the effects of magnetic field

- Electron beams may experience tilts up to 18 degrees (detectable ?)
- Electrons under the influence of the electric fields near Eth require a larger distance to avalanche multiply
- The average energy of the runaway electrons will decrease due to more collisions with air in the tilt direction
